## 1 Complex numbers (warm-up)

$$z = a + ib = re^{i\theta}$$

with

$$i^2 = -1$$

where (conversion by *Euler identity*)

$$e^{i\theta} = \cos \theta + i \sin \theta$$

Sidequest: derive conversion between  $(a, b) \rightsquigarrow (r, \theta)$

Each complex number has its complex conjugate (will be very useful, as then we can speak in only complex numbers)

$$\bar{z} \equiv z^* = a - ib = re^{-i\theta}$$

For the sake of communication, the following notation is used:

$$\Re(z) := a; \quad \Im(z) := b; \quad |z| := r; \quad \arg z := \theta$$

facts to prove:

- $(z_1 \pm z_2)^* = z_1^* \pm z_2^*$
- $(z_1 z_2)^* = z_1^* z_2^*$
- $(1/z)^* = 1/z^*$
- $\begin{pmatrix} z_1 \\ z_2 \end{pmatrix}^* = \begin{pmatrix} z_1^* \\ z_2^* \end{pmatrix}$

## 2 Geometry (pro-tip: only lazy solves)

We mark points of the plane with their corresponding complex number ( $a$  being the  $x$  coordinate,  $b$  being the  $y$  one) and name them by the corresponding non-Capital letter (number  $o$  for point  $O$ , etc.)

- Take a point  $z$  on the unit circle ( $|z| = 1$ ). Then  $z^* = \frac{1}{z}$ .
- $zz^* = |z|^2$  (way to measure (equality of) lengths)

Figure 1: Different complex number interpretations

- $\frac{z}{z^*} = e^{2i \arg z}$  (way to measure (equality of) angles)
- Particular cases for angles:  $e^{2i\pi} = 1, e^{i\pi} = -1$
- A segment  $AB$  is very well represented by  $b - a$ .
- Length of a segment  $AB$ :

$$|AB|^2 = (a - b)(a^* - b^*)$$

- Parallel lines  $AB$  and  $CD$  by equating their directions:

$$\frac{a - b}{a^* - b^*} = \frac{c - d}{c^* - d^*}$$

- Claim that  $AB \parallel AC$  means  $A, B, C$  being colinear.
- Perpendicular lines  $AB$  and  $CD$  by noting their directions opposite by sign:

$$\frac{a - b}{a^* - b^*} = -\frac{c - d}{c^* - d^*}$$

- Useful identity, when you have  $B, C$  on the unit circle:

$$\frac{b - c}{b^* - c^*} = -bc$$

- Homothety (ratios) work nicely: midpoint of  $AB$  is
- Mass centre of a triangle  $ABC$
- Orthocentre  $H$  of  $ABC$ :

### 3 Problems (feel free to later try synthetically as well)

1. Derive an expression for the intersection of two chords  $AB$  and  $CD$  of the unit circle.
2. Let  $H$  be the orthocentre of triangle  $ABC$ . Show that its reflections over  $BC$  (called  $R_1$ ) and over the midpoint of  $BC$  (called  $R_2$ ) both lie on the circumcircle
3. Prove Euler's line ( $O, H, G$  are colinear)
4.  $P$  and  $Q$  are on the unit circle. Derive the expression for the intersection of the tangents through  $P$  and  $Q$  (also called the polar of  $PQ$ ).
5. Let  $AC$  be the diameter of a circle, containing points  $A, B, C, D$ . Let  $X$  the intersection of  $AB$  and  $CD$ ,  $Y$  be the intersection of tangents through  $B$  and  $D$ . Prove that  $|AC| = |XY|$ .
6. Let  $D, E$  be feet of altitudes from  $A, B$  of triangle  $ABC$ ,  $H$  its orthocentre.  $DE$  intersects  $AB$  at  $K$ . Prove that the median  $CM \perp HK$ .
7. Derive the expression for the feet of angle bisectors  $D, E, F$  of triangle  $ABC$  on the unit circle; the expression for the incentre. (think of smarter ways to do that)
8. [Napoleonian triangles] Let  $ABC$  be a triangle. On its three sides we erect equilateral triangles  $ABF, BCD, CAE$ . Prove that the centres of these triangles are the vertices of an equilateral triangle.
9. [IMO 2009] Let  $ABC$  be a triangle with circumcentre  $O$ . The points  $P$  and  $Q$  are interior points of the sides  $CA$  and  $AB$  respectively. Let  $K, L$  and  $M$  be the midpoints of the segments  $BP, CQ$  and  $PQ$ . respectively, and let  $\Gamma$  be the circle passing through  $K, L$  and  $M$ . Suppose that the line  $PQ$  is tangent to the circle  $\Gamma$ . Prove that  $OP = OQ$ .
10. [IMO 2012] Given triangle  $ABC$  the point  $J$  is the centre of the excircle opposite the vertex  $A$ . This excircle is tangent to the side  $BC$  at  $M$ , and to the lines  $AB$  and  $AC$  at  $K$  and  $L$ , respectively. The lines  $LM$  and  $BJ$  meet at  $F$ , and the lines  $KM$  and  $CJ$  meet at  $G$ . Let  $S$  be the point of intersection of the lines  $AF$  and  $BC$ , and let  $T$  be the point of intersection of the lines  $AG$  and  $BC$ . Prove that  $M$  is the midpoint of  $ST$ .
